TITLE

Automated File Transferring
without internet

PROBLEM STATEMENT

Transfer of a file from one system to another system through using a device which is capable of switch on and off but the condition is at a time only one system will be on while transferring and another system will be off same as for the second system and the condition used here:-

1. The file transferred and received should know the system without the user intervention.
2. If transfer stops in between, how will the system know which files were already transferred and from where to continue.
3. Only particular extensions to be transferred, like PDFs, EXE files.

PROJECT TIMELINE

Week 1

Studied the problem statement and gathered requirements. Identified the need for automatic USB detection, file transfer between systems, extension-based filtering, and transfer resumption after interruption. Prepared the basic system design and workflow.

Week 2

Designed and implemented the file filtering mechanism. Configured the system to scan files and transfer only specified extensions such as .pdf, .exe, .txt, and other approved file types while ignoring unsupported files.

Week 3

Developed the automatic file transfer process and transfer log mechanism. The system was designed to record successfully transferred files, enabling tracking of transfer progress without user intervention.

Week 4

Implemented and tested the resume functionality. Simulated interruptions such as power failure and USB removal to verify that the system could identify already transferred files from the log and continue the transfer from the last successful point. Evaluated the overall performance and reliability of the system.

PROJECT GOAL

- To develop an automated USB-based file transfer system that can detect, receive, and transfer files between two systems without requiring any manual user intervention, making the process efficient and user-friendly.
 - To ensure reliable and secure file transfer by allowing only predefined file types (such as PDF, EXE, and TXT files) and by maintaining a transfer log that enables the system to resume from the last successful transfer point in case of any interruption.
-

RESULT

Automated and Efficient FileTransfer

The developed system successfully achieved automated file transfer between two systems using a USB device without requiring any user intervention. The system was able to detect the USB device, identify the source and destination locations, and initiate the transfer process automatically. This eliminated the need for manual file selection, copying, and monitoring, thereby reducing human effort and the possibility of errors. The automated workflow improved the overall efficiency of file transfer and demonstrated that data can be exchanged between systems in a reliable and user-friendly manner.

Reliable Transfer with File Filtering and Recovery Mechanism

The system successfully implemented file filtering and transfer recovery features as specified in the problem statement. Only files with predefined extensions, such as PDF, EXE, TXT, and other approved formats, were selected for transfer, while unsupported file types were ignored. In addition, the system maintained a transfer log that recorded the status of each successfully transferred file. During testing, when interruptions such as system shutdown, power failure, or USB disconnection were simulated, the system was able to identify the files that had already been transferred and resume the transfer process from the last successful point. This prevented duplicate transfers, reduced the risk of data loss, and ensured the successful completion of file transfer operations even in unexpected situations. The results confirmed that the system is efficient, reliable, and capable of handling real- world file transfer requirements.

CONCLUSION

This project provides an automated and reliable file transfer system using a USB device. It transfers only selected file types, works without user intervention, and maintains a transfer log to track progress. In case of interruption, the system can resume from the last successful transfer point, ensuring efficient, secure, and duplicate-free file transfer between systems.
